

Programming Pearl: Do-it-yourself module types

ANONYMOUS AUTHOR(S)

Can parameterised records and algebraic datatypes be derived from one pragmatic declaration?

Record types give a universe of discourse, parameterised record types fix parts of that universe ahead of time, and algebraic datatypes give us first-class syntax, whence evaluators and optimisers.

The answer is in the affirmative. Besides a practical shared declaration interface, which is extensible in the language, we also find that common data structures correspond to simple theories.

1 INTRODUCTION

All too often, when we program, we write the same information two or more times in our code, in different guises. For example, in Haskell, we may write a class, a record to reify that class, and an algebraic type to give us a syntax for programs written using that class. In proof assistants, this tends to get worse rather than better, as parametrized records give us a means to “stage” information. From here on, we will use Agda-Norell [2007] for our examples.

Concretely, suppose we have two monoids $(M_1, _ \circ_1 _, \text{Id}_1)$ and $(M_2, _ \circ_2 _, \text{Id}_2)$, if we know that $\text{ceq} : M_1 \equiv M_2$ then it is “obvious” that $\text{Id}_2 \circ_2 (x \circ_1 \text{Id}_1) \equiv x$ for all $x : M_1$. However, as written, this does not type-check. This is because $_ \circ_2 _$ expects elements of M_2 but has been given an element of M_1 . Because we have ceq in hand, we can use subst to transport things around. The resulting formula then typechecks, but is hideous. “subst hell” only gets worse. Below, we use pointed magmas for brevity, as the problem is the same.

```
record Magma0 : Set1 where
  field
    Carrier : Set
    _∘_      : Carrier → Carrier → Carrier
    Id      : Carrier

module Akward-Formulation (A B : Magma0)
  (ceq : Magma0.Carrier A ≡ Magma0.Carrier B)
  where
    open Magma0 A renaming (Id to Id1; _∘_ to _∘1_)
    open Magma0 B renaming (Id to Id2; _∘_ to _∘2_)

    claim : ∀ x → Id2 ∘2 subst id ceq (x ∘1 Id1) ≡ subst id ceq x
    claim = {!!}
```

It should not be this difficult to state a trivial fact. We could make things artificially prettier by defining coe to be subst id ceq without changing the heart of the matter. But if Magma_0 is the definition used in the library we are using, we are stuck with it, if we want to be compatible with other work.

Ideally, we would prefer to be able to express that the carriers are shared “on the nose”, which can be done as follows:

```

53 record Magma1 (Carrier : Set) : Set where
54   field
55     _%_      : Carrier → Carrier → Carrier
56     Id       : Carrier
57
58
59 module Nicer
60   (M : Set)    {- The shared carrier -}
61   (A B : Magma1 M)
62   where
63     open Magma1 A renaming (Id to Id1; _%_ to _%1_ )
64     open Magma1 B renaming (Id to Id2; _%_ to _%2_ )
65
66
67
68   claim : ∀ x → Id2 %2 (x %1 Id1) ≡ x
69   claim = {!!}
70

```

This is the formaluation we expected, without noise. Thus it seems that it would be better to expose the carrier. But, before long, we'd find a different concept, such as homomorphism, which are awkward in this way, and cleaner using the first approach. These two approaches are called *bundled* and *unbundled* respectively ?.

The definitions of homomorphism themselves (see below) is not so different, but the definition of composition already starts to be quite unwieldly.

```

77 record Hom0 (A B : Magma0) : Set where ...
78
79 record Hom1 {M1 M2 : Set} (A : Magma1 M1) (B : Magma1 M2) : Set where ...
80
81 composition0 : ∀ {A B C} → Hom0 A B → Hom0 B C → Hom0 A C
82 composition0 = {!!}
83
84
85 composition1 : ∀ {M1 M2 M3} {A : Magma1 M1} {B : Magma1 M2} {C : Magma1 M3}
86   → Hom1 A B → Hom1 B C → Hom1 A C
87 composition1 = {!!}
88

```

So not only are there no general rules for when the bundle or not, it is in fact guaranteed that any given choice will be sub-optimal for certain applications. Furthermore, these types are equivalent, as we can “pack away” an exposed piece, e.g., $\text{Monoid}_0 \cong \sum M : \text{Set} \bullet \text{Monoid}_1 M$. The developers of the Agda standard library [agd](#) [2020] have chosen to expose all types and function symbols while bundling up the proof obligations at one level, and also provide a fully bundled form as a wrapper. This is also the method chosen in Lean [Hales 2018], and in Coq [Spitters and van der Weegen 2011].

While such a choice is workable, it is still not optimal. There are bundling variants that are unavailable, and would be more convenient for certain application.

We will show an automatic technique for unbundling data at will; thereby resulting in *bundling-independent representations* and in *delayed unbundling*. Our contributions are to show:

- (1) Languages with sufficiently powerful type systems and meta-programming can conflate record and term datatype declarations into one practical interface. In addition, the contents of these grouping mechanisms may be function

symbols as well as propositional invariants —an example is shown at the end of 3. We identify the problem and the subtleties in shifting between representations in Section 2.

- (2) Parameterised records can be obtained on-demand from non-parameterised records (Section 3).
- As with Magma_0 , the traditional approach [Gross et al. 2014] to unbundling a record requires the use of transport along propositional equalities, with trivial refl -exivity proofs. In Section 3, we develop a combinator, $_:\text{waist}_$, which removes the boilerplate necessary at the type specialisation location as well as at the instance declaration location.
- (3) Programming with fixed-points of unary type constructors can be made as simple as programming with term datatypes (Section 4).

As an application, in Section 5 we show that the resulting setup applies as a semantics for a declarative pre-processing tool that accomplishes the above tasks.

For brevity, and accessibility, a number of definitions are elided and only [dashed pseudo-code] is presented in the paper, with the understanding that such functions need to be extended homomorphically over all possible term constructors of the host language. Enough is shown to communicate the techniques and ideas, as well as to make the resulting library usable. The details, which users do not need to bother with, can be found in the appendices.

2 THE PROBLEMS

There are a number of problems, with the number of parameters being exposed being the pivotal concern. To exemplify the distinctions at the type level as more parameters are exposed, consider the following approaches to formalising a dynamical system —a collection of states, a designated start state, and a transition function.

```

record DynamicSystem0 : Set1 where
  field
    State : Set
    start  : State
    next   : State → State

record DynamicSystem1 (State : Set) : Set where
  field
    start : State
    next  : State → State

record DynamicSystem2 (State : Set) (start : State) : Set where
  field
    next : State → State

```

Each DynamicSystem_i is a type constructor of i -many arguments; but it is the types of these constructors that provide insight into the sort of data they contain:

Type	Kind
DynamicSystem_0	Set_1
DynamicSystem_1	$\Pi X : \text{Set} \bullet \text{Set}$
DynamicSystem_2	$\Pi X : \text{Set} \bullet \Pi x : X \bullet \text{Set}$

We shall refer to the concern of moving from a record to a parameterised record as **the unbundling problem** [Garillot et al. 2009]. For example, moving from the *type* Set_1 to the *function type* $\prod X : \text{Set} \bullet \text{Set}$ gets us from DynamicSystem_0 to something resembling DynamicSystem_1 , which we arrive at if we can obtain a *type constructor* $\lambda X : \text{Set} \bullet \dots$. We shall refer to the latter change as *reification* since the result is more concrete, it can be applied; it will be denoted by $\prod \rightarrow \lambda$. To clarify this subtlety, consider the following forms of the polymorphic identity function. Notice that id_i *exposes* i -many details at the type level to indicate the sort it consists of. However, notice that id_0 is a type of functions whereas id_1 is a function on types. Indeed, the latter two are derived from the first one: $\text{id}_{i+1} = \prod \rightarrow \lambda \text{id}_i$. The latter identity is proven by reflexivity in the appendices.

```

id0 : Set1
id0 =  $\prod X : \text{Set} \bullet \prod e : X \bullet X$ 

id1 :  $\prod X : \text{Set} \bullet \text{Set}$ 
id1 =  $\lambda (X : \text{Set}) \rightarrow \prod e : X \bullet X$ 

id2 :  $\prod X : \text{Set} \bullet \prod e : X \bullet \text{Set}$ 
id2 =  $\lambda (X : \text{Set}) (e : X) \rightarrow X$ 

```

Of course, there is also the need for descriptions of values, which leads to the following term datatypes. We shall refer to the shift from record types to algebraic data types as **the termtype problem**. Our aim is to obtain all of these notions —of ways to group data together— from a single user-friendly context declaration, using monadic notation.

3 MONADIC NOTATION

There is little use in an idea that is difficult to use in practice. As such, we conflate records and termtypes by starting with an ideal syntax they would share, then derive the necessary artefacts that permit it. Our choice of syntax is monadic do-notation [Moggi 1991; ?]:

```

DynamicSystem : Context  $\ell_1$ 
DynamicSystem = do State  $\leftarrow \text{Set}$ 
                  start  $\leftarrow \text{State}$ 
                  next  $\leftarrow (\text{State} \rightarrow \text{State})$ 
                  End

```

Here `Context`, `End`, and the underlying monadic bind operator are unknown. Since we want to be able to *expose* a number of fields at will, we may take `Context` to be types indexed by a number denoting exposure. Moreover, since records are a product type, we expect there to be a recursive definition whose base case will be the essential identity of products, the unit type $\mathbb{1}$.

Table 1. Elaborations of `DynamicSystem` at various exposure levels

Exposure	Elaboration
0	$\sum \text{State} : \text{Set} \bullet \sum \text{start} : X \bullet \sum \text{next} : \text{State} \rightarrow \text{State} \bullet \mathbb{1}$
1	$\prod \text{State} : \text{Set} \bullet \sum \text{start} : X \bullet \sum \text{next} : \text{State} \rightarrow \text{State} \bullet \mathbb{1}$
2	$\prod \text{State} : \text{Set} \bullet \prod \text{start} : X \bullet \sum \text{next} : \text{State} \rightarrow \text{State} \bullet \mathbb{1}$
3	$\prod \text{State} : \text{Set} \bullet \prod \text{start} : X \bullet \prod \text{next} : \text{State} \rightarrow \text{State} \bullet \mathbb{1}$

With these elaborations of `DynamicSystem` to guide the way, we resolve two of our unknowns.

```

{- “Contexts” are exposure-indexed types -}
Context = λ ℓ → ℕ → Set ℓ

{- Every type is a context -}
‘_ : ∀ {ℓ} → Set ℓ → Context ℓ
‘ S = λ _ → S

{- The “empty context” is the unit type -}
End : ∀ {ℓ} → Context ℓ
End = ‘ 1

```

It remains to identify the definition of the underlying bind operation $\gg=$. Classically, for a type constructor m , bind is typed $\forall \{X \ Y : \text{Set}\} \rightarrow m \ X \rightarrow (X \rightarrow m \ Y) \rightarrow m \ Y$. It allows one to “extract an X -value for later use” in the $m \ Y$ context. Since our $m = \text{Context}$ is from levels to types, we need to slightly alter bind’s typing.

```

_>>=_ : ∀ {a b}
  → (Γ : Context a)
  → (∀ {n} → Γ n → Context b)
  → Context (a ⊔ b)

(Γ >>= f) zero    = Σ γ : Γ 0 • f γ 0
(Γ >>= f) (suc n) = Π γ : Γ n • f γ n

```

The definition here accounts for the current exposure index: If zero, we have *record types*, otherwise *function types*. Using this definition, the above dynamical system context would need to be expressed using the lifting quote operation.

```

‘ Set >>= λ State → ‘ State >>= λ start → ‘ (State → State) >>= λ next → End
{- or -}
do State ← ‘ Set
  start ← ‘ State
  next ← ‘ (State → State)
End

```

Interestingly [Bird 2009; Hudak et al. 2007], use of `do`-notation in preference to bind, $\gg=$, was suggested by John Launchbury in 1993 and was first implemented by Mark Jones in Gofer. Anyhow, with our goal of practicality in mind, we shall “build the lifting quote into the definition” of bind: With this definition, the above declaration `DynamicSystem`

```

_>>=_ : ∀ {a b}
  → (Γ : Set a) -- Main difference
  → (Γ → Context b)
  → Context (a ⊔ b)

(Γ >>= f) zero    = Σ γ : Γ • f γ 0
(Γ >>= f) (suc n) = Π γ : Γ • f γ n

```

Listing 1. Semantics: Context `do`-syntax is interpreted as Π - Σ -types

typechecks. However, $\text{DynamicSystem } i \not\cong \text{DynamicSystem}_i$, instead $\text{DynamicSystem } i$ are “factories”: Given i -many arguments, a product value is formed. What if we want to *instantiate* some of the factory arguments ahead of time?

```

261  $\mathcal{N}_0$  : DynamicSystem 0    {- See the elaborations table above -}
262
263
264  $\mathcal{N}_0 = \mathbb{N}$  , 0 , suc , tt
265
266
267  $\mathcal{N}_1$  : DynamicSystem 1
268
269  $\mathcal{N}_1 = \lambda \text{ State} \rightarrow ???$  {- Impossible to complete if “State” is empty! -}
270
271 {- “Instantiating” X to be  $\mathbb{N}$  in “DynamicSystem 1” -}
272
273  $\mathcal{N}_1' : \text{let State} = \mathbb{N} \text{ in } \Sigma \text{ start} : \text{State} \bullet \Sigma s : (\text{State} \rightarrow \text{State}) \bullet \mathbb{1}$ 
274
275  $\mathcal{N}_1' = 0$  , suc , tt

```

It seems what we need is a method, say $\Pi \rightarrow \lambda$, that takes a Π -type and transforms it into a λ -expression. One could use a universe, an algebraic type of codes denoting types, to define $\Pi \rightarrow \lambda$. However, one can no longer then easily use existing types since they are not formed from the universe’s constructors, thereby resulting in duplication of existing types via the universe encoding. This is not practical nor pragmatic.

As such, we are left with pattern matching on the language’s type formation primitives as the only reasonable approach. The method $\Pi \rightarrow \lambda$ is thus a macro that acts on the syntactic term representations of types. Below is main transformation—the details can be found in Appendix A.7.

$$\boxed{\Pi \rightarrow \lambda (\Pi a : A \bullet \tau) = (\lambda a : A \bullet \tau)}$$

That is, we walk along the term tree replacing occurrences of Π with λ . For example,

```

287  $\Pi \rightarrow \lambda (\Pi \rightarrow \lambda (\text{DynamicSystem } 2))$ 
288
289  $\equiv$  {- Definition of DynamicSystem at exposure level 2 -}
290  $\Pi \rightarrow \lambda (\Pi \rightarrow \lambda (\Pi X : \text{Set} \bullet \Pi s : X \bullet \Sigma n : X \rightarrow X \bullet \mathbb{1}))$ 
291
292  $\equiv$  {- Definition of  $\Pi \rightarrow \lambda$  -}
293  $\Pi \rightarrow \lambda (\lambda X : \text{Set} \bullet \Pi s : X \bullet \Sigma n : X \rightarrow X \bullet \mathbb{1})$ 
294
295  $\equiv$  {- Homomorphism of  $\Pi \rightarrow \lambda$  -}
296  $\lambda X : \text{Set} \bullet \Pi \rightarrow \lambda (\Pi s : X \bullet \Sigma n : X \rightarrow X \bullet \mathbb{1})$ 
297
298  $\equiv$  {- Definition of  $\Pi \rightarrow \lambda$  -}
299  $\lambda X : \text{Set} \bullet \lambda s : X \bullet \Sigma n : X \rightarrow X \bullet \mathbb{1}$ 

```

For practicality, `_ : waist_` is a macro acting on contexts that repeats $\Pi \rightarrow \lambda$ a number of times in order to lift a number of field components to the parameter level.

$$\boxed{\begin{array}{l} \tau : \text{waist } n = \Pi \rightarrow \lambda^n (\tau \text{ n}) \\ \text{-----} \\ f^0 x = x \\ \text{-----} \\ f^{n+1} x = f^n (f x) \end{array}}$$

We can now “fix arguments ahead of time”. Before such demonstration, we need to be mindful of our practicality goals: One declares a grouping mechanism with `do . . . End`, which in turn has its instance values constructed with `< . . . >`.

```

309 -- Expressions of the form “... , tt” may now be written “< ... >”
310
311 infixr 5 < _>

```

```

313   ⟨⟩ : ∀ {ℓ} → 1 {ℓ}
314   ⟨⟩ = tt
315
316   ⟨ : ∀ {ℓ} {S : Set ℓ} → S → S
317   ⟨ s = s
318
319
320   _⟩ : ∀ {ℓ} {S : Set ℓ} → S → S × (1 {ℓ})
321   s ⟩ = s , tt
322

```

The following instances of grouping types demonstrate how information moves from the body level to the parameter level.

```

326   N0 : DynamicSystem :waist 0
327   N0 = ⟨ N , 0 , suc ⟩
328
329
330   N1 : (DynamicSystem :waist 1) N
331   N1 = ⟨ 0 , suc ⟩
332
333
334   N2 : (DynamicSystem :waist 2) N 0
335   N2 = ⟨ suc ⟩
336
337
338   N3 : (DynamicSystem :waist 3) N 0 suc
339   N3 = ⟨ ⟩
340

```

Using `:waist i` we may fix the first i -parameters ahead of time. Indeed, the type `(DynamicSystem :waist 1) N` is the type of dynamic systems over carrier `N`, whereas `(DynamicSystem :waist 2) N 0` is the type of dynamic systems over carrier `N` and start state `0`.

Examples of the need for such on-the-fly unbundling can be found in numerous places in the Haskell standard library. For instance, the standard libraries [dat 2020] have two isomorphic copies of the integers, called `Sum` and `Product`, whose reason for being is to distinguish two common monoids: The former is for *integers with addition* whereas the latter is for *integers with multiplication*. An orthogonal solution would be to use contexts:

```

350   Monoid : ∀ ℓ → Context (ℓsuc ℓ)
351   Monoid ℓ = do Carrier ← Set ℓ
352               _⊕_      ← (Carrier → Carrier → Carrier)
353               Id       ← Carrier
354               leftId   ← ∀ {x : Carrier} → x ⊕ Id ≡ x
355               rightId  ← ∀ {x : Carrier} → Id ⊕ x ≡ x
356               assoc    ← ∀ {x y z} → (x ⊕ y) ⊕ z ≡ x ⊕ (y ⊕ z)
357               End {ℓ}
358

```

With this context, `(Monoid ℓ0 :waist 2) M ⊕` is the type of monoids over *particular* types `M` and *particular* operations `⊕`. Of-course, this is orthogonal, since traditionally unification on the carrier type `M` is what makes typeclasses and canonical structures [Mahboubi and Tassi 2013] useful for ad-hoc polymorphism.

4 TERMTYPES AS FIXED-POINTS

We have a practical monadic syntax for possibly parameterised record types that we would like to extend to termtypes. Algebraic data types are a means to declare concrete representations of the least fixed-point of a functor; see [Swierstra 2008] for more on this idea. In particular, the description language \mathbb{D} for dynamical systems, below, declares concrete constructors for a certain fixpoint F ; i.e., $\mathbb{D} \cong \text{Fix } F$ where:

```

data  $\mathbb{D} : \text{Set}$  where
  startD :  $\mathbb{D}$ 
  nextD  :  $\mathbb{D} \rightarrow \mathbb{D}$ 

F : Set  $\rightarrow$  Set
F =  $\lambda (D : \text{Set}) \rightarrow \mathbb{1} \uplus D$ 

data Fix (F : Set  $\rightarrow$  Set) : Set where
   $\mu : F (\text{Fix } F) \rightarrow \text{Fix } F$ 

```

The problem is whether we can derive F from DynamicSystem . Let us attempt a quick calculation.

```

do X  $\leftarrow$  Set; z  $\leftarrow$  X; s  $\leftarrow$  (X  $\rightarrow$  X); End
 $\Rightarrow$  {- Use existing interpretation to obtain a record. -}
 $\Sigma X : \text{Set} \bullet \Sigma z : X \bullet \Sigma s : (X \rightarrow X) \bullet \mathbb{1}$ 
 $\Rightarrow$  {- Pull out the carrier, “:waist 1”, to obtain a type constructor using “ $\Pi \rightarrow \lambda$ ”. -}
 $\lambda X : \text{Set} \bullet \Sigma z : X \bullet \Sigma s : (X \rightarrow X) \bullet \mathbb{1}$ 
 $\Rightarrow$  {- Termtypes target the declared type, so only their sources matter.
    E.g., ‘z : X’ is a nullary constructor targeting the carrier ‘X’.
    This introduces  $\mathbb{1}$  types, so any existing occurrences are dropped via  $\mathbb{0}$ . -}
 $\lambda X : \text{Set} \bullet \Sigma z : \mathbb{1} \bullet \Sigma s : X \bullet \mathbb{0}$ 
 $\Rightarrow$  {- Termtypes are sums of products. -}
 $\lambda X : \text{Set} \bullet \mathbb{1} \uplus X \uplus \mathbb{0}$ 
 $\Rightarrow$  {- Termtypes are fixpoints of type constructors. -}
Fix ( $\lambda X \bullet \mathbb{1} \uplus X$ ) -- i.e.,  $\mathbb{D}$ 

```

Since we may view an algebraic data-type as a fixed-point of the functor obtained from the union of the sources of its constructors, it suffices to treat the fields of a record as constructors, then obtain their sources, then union them. That is, since algebraic-datatype constructors necessarily target the declared type, they are determined by their sources. For example, considered as a unary constructor $\text{op} : A \rightarrow B$ targets the type termtype B and so its source is A . The details on the operations \Downarrow , $\Sigma \rightarrow \uplus$, sources shown below can be found in appendices A.3.4, A.11.4, and A.11.3, respectively.

```

 $\Downarrow \tau$  = “reduce all de brujin indices within  $\tau$  by 1”
 $\Sigma \rightarrow \uplus (\Sigma a : A \bullet Ba) = A \uplus \Sigma \rightarrow \uplus (\Downarrow Ba)$ 
sources ( $\lambda x : (\Pi a : A \bullet Ba) \bullet \tau$ ) = ( $\lambda x : A \bullet \text{sources } \tau$ )
sources ( $\lambda x : A \bullet \tau$ ) = ( $\lambda x : \mathbb{1} \bullet \text{sources } \tau$ )
termtype  $\tau = \text{Fix } (\Sigma \rightarrow \uplus (\text{sources } \tau))$ 

```

It is instructive to visually see how \mathbb{D} is obtained from `termtype` in order to demonstrate that this approach to algebraic data types is practical.

```

 $\mathbb{D}$  = termtype (DynamicSystem :waist 1)

-- Pattern synonyms for more compact presentation
pattern startD =  $\mu$  (inj1 tt)      -- :  $\mathbb{D}$ 
pattern nextD e =  $\mu$  (inj2 (inj1 e)) -- :  $\mathbb{D} \rightarrow \mathbb{D}$ 

```

With the pattern declarations, we can actually use these more meaningful names, when pattern matching, instead of the seemingly daunting μ -inj-jections. For instance, we can immediately see that the natural numbers act as the description language for dynamical systems:

```

to :  $\mathbb{D} \rightarrow \mathbb{N}$ 
to startD = 0
to (nextD x) = suc (to x)

from :  $\mathbb{N} \rightarrow \mathbb{D}$ 
from zero = startD
from (suc n) = nextD (from n)

```

Readers whose language does not have `pattern` clauses need not despair. With the macro `[Inj n x = μ (inj2 " (inj1 x))]`, we may define `startD = Inj 0 tt` and `nextD e = Inj 1 e`—that is, constructors of termtypes are particular injections into the possible summands that the termtype consists of. Details on this macro may be found in appendix A.11.6.

5 RELATED WORKS

Surprisingly, conflating parameterised and non-parameterised record types with termtypes *within a language in a practical fashion* has not been done before.

The PackageFormer [Al-hassy 2019; Al-hassy et al. 2019] editor extension reads contexts—in nearly the same notation as ours—enclosed in dedicated comments, then generates and imports Agda code from them seamlessly in the background whenever typechecking transpires. The framework provides a fixed number of meta-primitives for producing arbitrary notions of grouping mechanisms, and allows arbitrary Emacs Lisp [Graham 1995] to be invoked in the construction of complex grouping mechanisms.

Table 2. Comparing the in-language Context mechanism with the PackageFormer editor extension

	PackageFormer	Contexts
Type of Entity	Preprocessing Tool	Language Library
Specification Language	Lisp + Agda	Agda
Well-formedness Checking	✗	✓
Termination Checking	✓	✓
Elaboration Tooltips	✓	✗
Rapid Prototyping	✓	✓ (Slower)
Usability Barrier	None	None
Extensibility Barrier	Lisp	Weak Metaprogramming

The original PackageFormer paper provided the syntax necessary to form useful grouping mechanisms but was shy on the semantics of such constructs. We have chosen the names of our combinators to closely match those of PackageFormer’s with an aim of furnishing the mechanism with semantics by construing the syntax as semantics-functions; i.e., we have a shallow embedding of PackageFormer’s constructs as Agda entities:

Table 3. Contexts as a semantics for PackageFormer constructs

Syntax	Semantics
PackageFormer	Context
:waist	:waist
\oplus	Forward function application
:kind	:kind, see below
:level	Agda built-in
:alter-elements	Agda macros

PackageFormer’s `_:kind_` meta-primitive dictates how an abstract grouping mechanism should be viewed in terms of existing Agda syntax. However, unlike PackageFormer, all of our syntax consists of legitimate Agda terms. Since language syntax is being manipulated, we are forced to define it as a macro:

```

data Kind : Set where
  'record   : Kind
  'typeclass : Kind
  'data     : Kind

C :kind 'record   = C 0
C :kind 'typeclass = C :waist 1
C :kind 'data     = termtype (C :waist 1)

```

We did not expect to be able to assign a full semantics to PackageFormer’s syntactic constructs due to Agda’s substantially weak metaprogramming mechanism. However, it is important to note that PackageFormer’s Lisp extensibility expedites the process of trying out arbitrary grouping mechanisms—such as partial-choices of pushouts and pullbacks along user-provided assignment functions—since it is all either string or symbolic list manipulation. On the Agda side, using contexts, it would require exponentially more effort due to the limited reflection mechanism and the intrusion of the stringent type system.

6 CONCLUSION

Starting from the insight that related grouping mechanisms could be unified, we showed how related structures can be obtained from a single declaration using a practical interface. The resulting framework, based on contexts, still captures the familiar record declaration syntax as well as the expressivity of usual algebraic datatype declarations—the minimal cost of using pattern declarations to aide as user-chosen constructor names. We believe that our approach to using contexts as general grouping mechanisms *with* a practical interface are interesting contributions.

We used the focus on practicality to guide the design of our context interface, and provided interpretations both for the rather intuitive “contexts are name-type records” view, and for the novel “contexts are fixed-points” view for termtypes. In addition, to obtain parameterised variants, we needed to explicitly form “contexts whose contents are

over a given ambient context”—e.g., contexts of vector spaces are usually discussed with the understanding that there is a context of fields that can be referenced— which we did using monads. These relationships are summarised in the following table.

Table 4. Contexts embody all kinds of grouping mechanisms

Concept	Concrete Syntax	Description
Context	$\text{do } S \leftarrow \text{Set}; s \leftarrow S; n \leftarrow (S \rightarrow S); \text{End}$	“name-type pairs”
Record Type	$\Sigma S : \text{Set} \bullet \Sigma s : S \bullet \Sigma n : S \rightarrow S \bullet \mathbb{1}$	“bundled-up data”
Function Type	$\Pi S \bullet \Sigma s : S \bullet \Sigma n : S \rightarrow S \bullet \mathbb{1}$	“a type of functions”
Type constructor	$\lambda S \bullet \Sigma s : S \bullet \Sigma n : S \rightarrow S \bullet \mathbb{1}$	“a function on types”
Algebraic datatype	$\text{data } \mathbb{D} : \text{Set} \text{ where } s : \mathbb{D}; n : \mathbb{D} \rightarrow \mathbb{D}$	“a descriptive syntax”

To those interested in exotic ways to group data together —such as, mechanically deriving product types and homomorphism types of theories— we offer an interface that is extensible using Agda’s reflection mechanism. In comparison with, for example, special-purpose preprocessing tools, this has obvious advantages in accessibility and semantics.

To Agda programmers, this offers a standard interface for grouping mechanisms that had been sorely missing, with an interface that is so familiar that there would be little barrier to its use. In particular, as we have shown, it acts as an in-language library for exploiting relationships between free theories and data structures. As we have only presented the high-level definitions of the core combinators, leaving the Agda-specific details to the appendices, it is also straightforward to translate the library into other dependently-typed languages.

7 OLD WHY SYNTAX

MAYBE_DELETE

The archetype for records and termtypes —algebraic data types— are monoids. They describe untyped compositional structures, such as programs in dynamically type-checked language. In turn, their termtype is linked lists which reify a monoid value —such as a program— as a sequence of values —i.e., a list of language instructions— which ‘evaluate’ to the original value. The shift to syntax gives rise to evaluators, optimisers, and constrained recursion-induction principles.

8 OLD GRAPH IDEAS

MAYBE_DELETE

8.1 From the old introduction section

For example, there are two ways to implement the type of graphs in the dependently-typed language Agda [Bove et al. 2009; Norell 2007]: Having the vertices be a parameter or having them be a field of the record. Then there is also the syntax for graph vertex relationships. Suppose a library designer decides to work with fully bundled graphs, `Graph0` below, then a user decides to write the function `comap`, which relabels the vertices of a graph, using a function `f` to transform vertices.

```

625 record Graph0 : Set1 where
626   constructor ⟨_,_⟩0
627   field
628     Vertex : Set
629     Edges : Vertex → Vertex → Set
630 comap0 : {A B : Set}
631   → (f : A → B)
632   → (Σ G : Graph0 • Vertex G ≡ B)
633   → (Σ H : Graph0 • Vertex H ≡ A)
634 comap0 {A} f (G , refl) = ⟨ A , (λ x y → Edges G (f x) (f y)) ⟩0 , refl

```

Since the vertices are packed away as components of the records, the only way for f to refer to them is to awkwardly refer to seemingly arbitrary types, only then to have the vertices of the input graph G and the output graph H be constrained to match the type of the relabelling function f . Without the constraints, we could not even write the function for Graph_0 . With such an importance, it is surprising to see that the occurrences of the constraint proofs are un insightful refl -exivity proofs.

What the user would really want is to unbundle Graph_0 at will, to expose the first argument, to obtain Graph_1 below. Then, in stark contrast, the implementation comap_1 does not carry any excesses baggage at the type level nor at the implementation level.

```

648 record Graph1 (Vertex : Set) : Set1 where
649   constructor ⟨_⟩1
650   field
651     Edges : Vertex → Vertex → Set
652 comap1 : {A B : Set}
653   → (f : A → B)
654   → Graph1 B
655   → Graph1 A
656 comap1 f ⟨ edges ⟩1 = ⟨ (λ x y → edges (f x) (f y)) ⟩1

```

With Graph_1 , one immediately sees that the comap operation “pulls back” the vertex type. Such an observation for Graph_0 is not as easy; requiring familiarity with quantifier laws such as the one-point rule and quantifier distributivity.

9 OLD FREE DATATYPES FROM THEORIES

MAYBE_DELETE

Astonishingly, useful programming datatypes arise from termtypes of theories (contexts). That is, if $C : \text{Set} \rightarrow \text{Context } \ell_0$ then $\mathbb{C}' = \lambda X \rightarrow \text{termtyp} (C X : \text{waist } 1)$ can be used to form ‘free, lawless, C -instances’. For instance, earlier we witnessed that the termtyp of dynamical systems is essentially the natural numbers.

To obtain trees over some ‘value type’ Ξ , one must start at the theory of “monoids containing a given set Ξ ”. Similarly, by starting at “theories of pointed sets over a given set Ξ ”, the resulting termtyp is the Maybe type constructor —another instructive exercise to the reader: Show that $\mathbb{P} \cong \text{Maybe}$.

```

673 PointedOver : Set → Context (ℓsuc ℓ0)
674 PointedOver Ξ = do Carrier ← Set ℓ0

```

Table 5. Data structures as free theories

Theory	Termtype
Dynamical Systems	\mathbb{N}
Pointed Structures	Maybe
Monoids	Binary Trees

```

point  ← Carrier
embed  ← ( $\exists$  → Carrier)
End

```

```

P : Set → Set
P X = termtype (PointedOver X :waist 1)

-- Pattern synonyms for more compact presentation
pattern nothingP =  $\mu$  (inj1 tt)      -- : P
pattern justP e   =  $\mu$  (inj2 (inj1 e)) -- : P → P

```

The final entry in the table is a well known correspondence, that we can, not only formally express, but also prove to be true. We present the setup and leave it as an instructive exercise to the reader to present a bijective pair of functions between \mathbb{M} and `TreeSkeleton`. Hint: Interactively case-split on values of \mathbb{M} until the declared patterns appear, then associate them with the constructors of `TreeSkeleton`.

```

M : Set
M = termtype (Monoid  $\ell_0$  :waist 1)

-- Pattern synonyms for more compact presentation
pattern emptyM      =  $\mu$  (inj1 tt)      -- : M
pattern branchM l r =  $\mu$  (inj2 (inj1 (l , r , tt))) -- : M → M → M
pattern absurdM a   =  $\mu$  (inj2 (inj2 (inj2 (inj2 a)))) -- absurd values of 0

data TreeSkeleton : Set where
  empty  : TreeSkeleton
  branch : TreeSkeleton → TreeSkeleton → TreeSkeleton

```

9.1 Collection Context

```

Collection :  $\forall \ell \rightarrow$  Context ( $\ell$ suc  $\ell$ )
Collection  $\ell$  = do
  Elem    ← Set  $\ell$ 
  Carrier ← Set  $\ell$ 
  insert  ← (Elem → Carrier → Carrier)
   $\emptyset$    ← Carrier
  isEmpty ← (Carrier → Bool)

```

```

729     insert-nonEmpty ← ∀ {e : Elem} {x : Carrier} → isEmpty (insert e x) ≡ false
730   End {ℓ}
731
732   ListColl : {ℓ : Level} → Collection ℓ 1
733   ListColl E = ⟨ List E
734     , _::_
735     , []
736     , (λ { [] → true; _ → false})
737     , (λ {x} {x = x₁} → refl)
738   ⟩
739
740   NCollection = (Collection ℓ₀ :waist 2)
741     ("Elem"      = Digit)
742     ("Carrier" = N)
743
744   --
745   -- i.e., (Collection ℓ₀ :waist 2) Digit N
746
747   stack : NCollection
748   stack = ⟨ "insert"      = (λ d s → suc (10 * s + #→N d))
749     , "empty stack" = 0
750     , "is-empty"    = (λ { 0 → true; _ → false})
751     -- Properties --
752     , (λ {d : Digit} {s : N} → refl {x = false})
753   ⟩

```

9.2 Elem, Carrier, insert projections

```

761   Elem      : ∀ {ℓ} → Collection ℓ 0 → Set ℓ
762   Elem      = λ C → Field 0 C
763
764   Carrier   : ∀ {ℓ} → Collection ℓ 0 → Set ℓ
765   Carrier₁  : ∀ {ℓ} → Collection ℓ 1 → (γ : Set ℓ) → Set ℓ
766   Carrier₁' : ∀ {ℓ} {γ : Set ℓ} (C : (Collection ℓ :waist 1) γ) → Set ℓ
767
768   Carrier   = λ C → Field 1 C
769   Carrier₁  = λ C γ → Field 0 (C γ)
770   Carrier₁' = λ C → Field 0 C
771
772   insert    : ∀ {ℓ} (C : Collection ℓ 0) → (Elem C → Carrier C → Carrier C)
773   insert₁   : ∀ {ℓ} (C : Collection ℓ 1) (γ : Set ℓ) → γ → Carrier₁ C γ → Carrier₁ C γ
774   insert₁'  : ∀ {ℓ} {γ : Set ℓ} (C : (Collection ℓ :waist 1) γ) → γ → Carrier₁' C → Carrier₁' C

```

```

781      insert    = λ C    → Field 2 C
782      insert1  = λ C γ → Field 1 (C γ)
783      insert1' = λ C    → Field 1 C
784
785
786      insert2  : ∀ {ℓ} (C : Collection ℓ 2) (El Cr : Set ℓ) → El → Cr → Cr
787      insert2' : ∀ {ℓ} {El Cr : Set ℓ} (C : (Collection ℓ :waist 2) El Cr) → El → Cr → Cr
788
789
790      insert2 = λ C El Cr → Field 0 (C El Cr)
791      insert2' = λ C    → Field 0 C
792

```

10 OLD WHAT ABOUT THE META-LANGUAGE'S PARAMETERS?

MAYBE_DELETE

Besides :waist, another way to introduce parameters into a context grouping mechanism is to use the language's existing utility of parameterising a context by another type —as was done earlier in PointedOver.

For example, a pointed set needn't necessarily be terminated with End.

```

799      PointedSet : Context ℓ1
800      PointedSet = do Carrier ← Set
801                  point   ← Carrier
802                  End {ℓ1}
803

```

We instead form a grouping consisting of a single type and a value of that type, along with an instance of the parameter type Ξ .

```

807      PointedPF : (Ξ : Set1) → Context ℓ1
808      PointedPF Ξ = do Carrier ← Set
809                  point   ← Carrier
810                  ' Ξ
811

```

Clearly PointedPF $\mathbb{1} \approx$ PointedSet, so we have a more generic grouping mechanism. The natural next step is to consider other parameters such as PointedSet in-place of Ξ .

```

815      -- Convenience names
816      PointedSetr = PointedSet           :kind 'record
817      PointedPFr  = λ Ξ → PointedPF Ξ   :kind 'record
818
819
820      -- An extended record type: Two types with a point of each.
821      TwoPointedSets = PointedPFr PointedSetr
822
823
824      _ : TwoPointedSets
825      ≡ ( Σ Carrier1 : Set • Σ point1 : Carrier1
826          • Σ Carrier2 : Set • Σ point2 : Carrier2 •  $\mathbb{1}$  )
827      _ = refl
828
829
830      -- Here's an instance
831      one : PointedSet :kind 'record
832

```

```

833     one =  $\mathbb{B}$  , false , tt
834
835     -- Another; a pointed natural extended by a pointed bool,
836     -- with particular choices for both.
837
838     two : TwoPointedSets
839     two =  $\mathbb{N}$  , 0 , one
840

```

More generally, *record **structure** can be dependent on values:*

```

842     _PointedSets :  $\mathbb{N} \rightarrow \text{Set}_1$ 
843     zero   PointedSets = 1
844     suc n PointedSets = PointedPFr (n PointedSets)
845
846
847     _ : 4 PointedSets
848     ≡ (  $\sum$  Carrier1 : Set •  $\sum$  point1 : Carrier1
849         •  $\sum$  Carrier2 : Set •  $\sum$  point2 : Carrier2
850         •  $\sum$  Carrier3 : Set •  $\sum$  point3 : Carrier3
851         •  $\sum$  Carrier4 : Set •  $\sum$  point4 : Carrier4 • 1 )
852
853     _ = refl
854

```

Using traditional grouping mechanisms, it is difficult to create the family of types n PointedSets since the number of fields, $2 \times n$, depends on n .

It is interesting to note that the termtype of PointedPF is the same as the termtype of PointedOver, the Maybe type constructor!

```

855
856
857
858
859
860
861     PointedD : (X : Set)  $\rightarrow \text{Set}_1$ 
862     PointedD X = termtype (PointedPF (Lift _ X) :waist 1)
863
864
865     -- Pattern synonyms for more compact presentation
866     pattern nothingP =  $\mu$  (inj1 tt)
867     pattern justP x   =  $\mu$  (inj2 (lift x))
868
869
870     casingP :  $\forall \{X\} (e : \text{PointedD } X)$ 
871          $\rightarrow (e \equiv \text{nothingP}) \uplus (\sum x : X \bullet e \equiv \text{justP } x)$ 
872     casingP nothingP = inj1 refl
873     casingP (justP x) = inj2 (x , refl)
874

```

11 OLD NEXT STEPS

MAYBE_DELETE

We have shown how a bit of reflection allows us to have a compact, yet practical, one-stop-shop notation for records, typeclasses, and algebraic data types. There are a number of interesting directions to pursue:

- How to write a function working homogeneously over one variation and having it lift to other variations.
 - Recall the comap from the introductory section was written over `Graph : kind 'typeclass`; how could that particular implementation be massaged to work over `Graph : kind k` for any k .

- The current implementation for deriving termtypes presupposes only one carrier set positioned as the first entity in the grouping mechanism.
 - How do we handle multiple carriers or choose a carrier from an arbitrary position or by name? PackageFormer handles this by comparing names.
- How do we lift properties or invariants, simple \equiv -types that ‘define’ a previous entity to be top-level functions in their own right?

Lots to do, so little time.

A APPENDICES

Below is the entirety of the Context library discussed in the paper proper.

```
module Context where
```

A.1 Imports

```
open import Level renaming (_⊥_ to _⊥_, suc to ℓsuc; zero to ℓ₀)
open import Relation.Binary.PropositionalEquality
open import Relation.Nullary

open import Data.Nat
open import Data.Fin as Fin using (Fin)
open import Data.Maybe hiding (_>=>_)

open import Data.Bool using (Bool ; true ; false)
open import Data.List as List using (List ; [] ; _::_ ; _::^f_ ; sum)

ℓ₁ = Level.suc ℓ₀
```

A.2 Quantifiers $\Pi:\bullet/\Sigma:\bullet$ and Products/Sum

We shall use Z-style quantifier notation [Woodcock and Davies 1996] in which the quantifier dummy variables are separated from the body by a large bullet.

In Agda, we use $\backslash :$ to obtain the “ghost colon” since standard colon $:$ is an Agda operator.

Even though Agda provides $\forall (x : \tau) \rightarrow fx$ as a built-in syntax for Π -types, we have chosen the Z-style one below to mirror the notation for Σ -types, which Agda provides as `record` declarations. In the paper proper, in the definition of `bind`, the subtle shift between Σ -types and Π -types is easier to notice when the notations are so similar that only the quantifier symbol changes.

```
open import Data.Empty using (⊥)
open import Data.Sum
open import Data.Product
open import Function using (_o_)

Σ:• : ∀ {a b} (A : Set a) (B : A → Set b) → Set _
Σ:• = Σ

infix -666 Σ:•
syntax Σ:• A (λ x → B) = Σ x : A • B

Π:• : ∀ {a b} (A : Set a) (B : A → Set b) → Set _
Π:• A B = (x : A) → B x
```

```

937
938   infix -666 Π:•
939   syntax Π:• A (λ x → B) = Π x : A • B
940
941   record T {ℓ} : Set ℓ where
942     constructor tt
943
944   1 = T {ℓ0}
945   0 = ⊥
946

```

A.3 Reflection

We form a few metaprogramming utilities we would have expected to be in the standard library.

```

950   import Data.Unit as Unit
951   open import Reflection hiding (name; Type) renaming (>=>_ to >=>_m_)
952

```

A.3.1 Single argument application.

```

953
954   _app_ : Term → Term → Term
955   (def f args) app arg' = def f (args ::r arg (arg-info visible relevant) arg')
956   (con f args) app arg' = con f (args ::r arg (arg-info visible relevant) arg')
957   {-# CATCHALL #-}
958   tm app arg' = tm
959

```

Notice that we maintain existing applications:

$$\text{quoteTerm } (f \ x) \ \text{app} \ \text{quoteTerm } y \ \approx \ \text{quoteTerm } (f \ x \ y)$$

A.3.2 Reify \mathbb{N} term encodings as \mathbb{N} values.

```

963
964
965   toN : Term → ℕ
966   toN (lit (nat n)) = n
967   {-# CATCHALL #-}
968   toN _ = 0
969

```

A.3.3 The Length of a Term.

```

970
971   arg-term : ∀ {ℓ} {A : Set ℓ} → (Term → A) → Arg Term → A
972   arg-term f (arg i x) = f x
973
974   {-# TERMINATING #-}
975   lengthℓ : Term → ℕ
976   lengthℓ (var x args)      = 1 + sum (List.map (arg-term lengthℓ ) args)
977   lengthℓ (con c args)      = 1 + sum (List.map (arg-term lengthℓ ) args)
978   lengthℓ (def f args)      = 1 + sum (List.map (arg-term lengthℓ ) args)
979   lengthℓ (lam v (abs s x)) = 1 + lengthℓ x
980   lengthℓ (pat-lam cs args) = 1 + sum (List.map (arg-term lengthℓ ) args)
981   lengthℓ (Π[ x : A ] Bx)   = 1 + lengthℓ Bx
982   {-# CATCHALL #-}
983   -- sort, lit, meta, unknown
984   lengthℓ t = 0
985

```

Here is an example use:

```

986   _ : lengthℓ (quoteTerm (Σ x : ℕ • x ≡ x)) ≡ 10
987   _ = refl
988

```

A.3.4 Decreasing de Bruijn Indices. Given a quantification $(\oplus x : \tau \bullet fx)$, its body fx may refer to a free variable x . If we decrement all de Bruijn indices fx contains, then there would be no reference to x .

```

var-dec0 : (fuel : ℕ) → Term → Term
var-dec0 zero t = t
-- Let's use an "impossible" term.
var-dec0 (suc n) (var zero args) = def (quote ⊥) []
var-dec0 (suc n) (var (suc x) args) = var x args
var-dec0 (suc n) (con c args) = con c (map-Args (var-dec0 n) args)
var-dec0 (suc n) (def f args) = def f (map-Args (var-dec0 n) args)
var-dec0 (suc n) (lam v (abs s x)) = lam v (abs s (var-dec0 n x))
var-dec0 (suc n) (pat-lam cs args) = pat-lam cs (map-Args (var-dec0 n) args)
var-dec0 (suc n) (Π[ s : arg i A ] B) = Π[ s : arg i (var-dec0 n A) ] var-dec0 n B
{-# CATCHALL #-}
-- sort, lit, meta, unknown
var-dec0 n t = t

```

In the paper proper, `var-dec` was mentioned once under the name \Downarrow .

```

var-dec : Term → Term
var-dec t = var-dec0 (lengtht t) t

```

Notice that we made the decision that x , the body of $(\oplus x \bullet x)$, will reduce to \emptyset , the empty type. Indeed, in such a situation the only Debrujin index cannot be reduced further. Here is an example:

```

_ : ∀ {x : ℕ} → var-dec (quoteTerm x) ≡ quoteTerm ⊥
_ = refl

```

A.4 Context Monad

```

Context = λ ℓ → ℕ → Set ℓ

infix -1000 ` _
`_ : ∀ {ℓ} → Set ℓ → Context ℓ
`S = λ _ → S

End : ∀ {ℓ} → Context ℓ
End = ` ⊤

End0 = End {ℓ0}

_>>=_ : ∀ {a b}
  → (Γ : Set a) -- Main difference
  → (Γ → Context b)
  → Context (a ⊔ b)
(Γ >>= f) N.zero = Σ γ : Γ • f γ ⊥
(Γ >>= f) (suc n) = (γ : Γ) → f γ n

```

A.5 ⟨⟩ Notation

As mentioned, grouping mechanisms are declared with `do . . . End`, and instances of them are constructed using `⟨ . . . ⟩`.

```

-- Expressions of the form "... , tt" may now be written "{ ... }"
infixr 5 ⟨ _⟩
⟨⟩ : ∀ {ℓ} → T {ℓ}
⟨⟩ = tt

```

```

1041   < : ∀ {ℓ} {S : Set ℓ} → S → S
1042   < s = s
1043
1044   <_> : ∀ {ℓ} {S : Set ℓ} → S → S × T {ℓ}
1045   s > = s , tt

```

A.6 DynamicSystem Context

```

1047   DynamicSystem : Context (ℓsuc Level.zero)
1048   DynamicSystem = do X ← Set
1049                   z ← X
1050                   s ← (X → X)
1051                   End {Level.zero}
1052
1053   -- Records with n-Parameters, n : 0..3
1054   A B C D : Set1
1055   A = DynamicSystem 0 -- Σ X : Set • Σ z : X • Σ s : X → X • T
1056   B = DynamicSystem 1 -- (X : Set) → Σ z : X • Σ s : X → X • T
1057   C = DynamicSystem 2 -- (X : Set) (z : X) → Σ s : X → X • T
1058   D = DynamicSystem 3 -- (X : Set) (z : X) → (s : X → X) → T

1123   $\mathcal{N}^3$  :  $D' \mathbb{N} \emptyset \text{suc}$ 
1124   $\mathcal{N}^3$  =  $\langle \rangle$ 

```

It may be the case that $\Gamma \emptyset \equiv \Gamma : \text{waist } 0$ for every context Γ .

```

1125  _ : DynamicSystem 0  $\equiv$  DynamicSystem :waist 0
1126  _ = refl
1127

```

A.10 Field projections

```

1129  Field0 :  $\mathbb{N} \rightarrow \text{Term} \rightarrow \text{Term}$ 
1130  Field0 zero c = def (quote proj1) (arg (arg-info visible relevant) c :: [])
1131  Field0 (suc n) c = Field0 n (def (quote proj2) (arg (arg-info visible relevant) c :: []))
1132
1133  macro
1134  Field :  $\mathbb{N} \rightarrow \text{Term} \rightarrow \text{Term} \rightarrow \text{TC Unit.T}$ 
1135  Field n t goal = unify goal (Field0 n t)
1136

```

A.11 Termtypes

Using the guide, ??, outlined in the paper proper we shall form D_i for each stage in the calculation.

A.11.1 Stage 1: Records.

```

1142   $D_1$  = DynamicSystem 0
1143

```

```

1145      1-records : D1 ≡ (Σ X : Set • Σ z : X • Σ s : (X → X) • T)
1146      1-records = refl
1147

```

A.11.2 Stage 2: Parameterised Records.

```

1149      D2 = DynamicSystem :waist 1
1150
1151      2-funcs : D2 ≡ (λ (X : Set) → Σ z : X • Σ s : (X → X) • T)
1152      2-funcs = refl
1153

```

A.11.3 Stage 3: Sources. Let's begin with an example to motivate the definition of sources.

```

1155      _ : quoteTerm (V {x : N} → N)
1156      ≡ pi (arg (arg-info hidden relevant) (quoteTerm N)) (abs "x" (quoteTerm N))
1157      _ = refl
1158

```

We now form two sources-helper utilities, although we suspect they could be combined into one function.

```

1159      sources0 : Term → Term
1160      -- Otherwise:
1161      sources0 (Π[ a : arg i A ] (Π[ b : arg _ Ba ] Cab)) =
1162          def (quote _X_) (vArg A
1163              :: vArg (def (quote _X_)
1164                  (vArg (var-dec Ba) :: vArg (var-dec (var-dec (sources0 Cab))) :: []))
1165              :: [])
1166      sources0 (Π[ a : arg (arg-info hidden _) A ] Ba) = quoteTerm 0
1167      sources0 (Π[ x : arg i A ] Bx) = A
1168      {-# CATCHALL #-}
1169      -- sort, lit, meta, unknown
1170      sources0 t = quoteTerm 1
1171
1172      {-# TERMINATING #-}
1173      sources1 : Term → Term
1174      sources1 (Π[ a : arg (arg-info hidden _) A ] Ba) = quoteTerm 0
1175      sources1 (Π[ a : arg i A ] (Π[ b : arg _ Ba ] Cab)) = def (quote _X_) (vArg A ::
1176          vArg (def (quote _X_) (vArg (var-dec Ba) :: vArg (var-dec (var-dec (sources0 Cab))) :: [])) :: [])
1177      sources1 (Π[ x : arg i A ] Bx) = A
1178      sources1 (def (quote Σ) (ℓ1 :: ℓ2 :: τ :: body))
1179          = def (quote Σ) (ℓ1 :: ℓ2 :: map-Arg sources0 τ :: List.map (map-Arg sources1) body)
1180      -- This function introduces 1s, so let's drop any old occurrences a la 0.
1181      sources1 (def (quote T) _) = def (quote 0) []
1182      sources1 (lam v (abs s x)) = lam v (abs s (sources1 x))
1183      sources1 (var x args) = var x (List.map (map-Arg sources1) args)
1184      sources1 (con c args) = con c (List.map (map-Arg sources1) args)
1185      sources1 (def f args) = def f (List.map (map-Arg sources1) args)
1186      sources1 (pat-lam cs args) = pat-lam cs (List.map (map-Arg sources1) args)
1187      {-# CATCHALL #-}
1188      -- sort, lit, meta, unknown
1189      sources1 t = t
1190

```

We now form the macro and some unit tests.

```

1190      macro
1191      sources : Term → Term → TC Unit.T
1192      sources tm goal = normalise tm >>= m λ tm' → unify (sources1 tm') goal
1193
1194      _ : sources (N → Set) ≡ N
1195      _ = refl
1196

```

```

1197   _ : sources (Σ x : (N → Fin 3) • N) ≡ (Σ x : N • N)
1198   _ = refl
1199
1200   _ : ∀ {ℓ : Level} {A B C : Set}
1201     → sources (Σ x : (A → B) • C) ≡ (Σ x : A • C)
1202   _ = refl
1203
1204   _ : sources (Fin 1 → Fin 2 → Fin 3) ≡ (Σ _ : Fin 1 • Fin 2 × 1)
1205   _ = refl
1206
1207   _ : sources (Σ f : (Fin 1 → Fin 2 → Fin 3 → Fin 4) • Fin 5)
1208     ≡ (Σ f : (Fin 1 × Fin 2 × Fin 3) • Fin 5)
1209   _ = refl
1210
1211   _ : ∀ {A B C : Set} → sources (A → B → C) ≡ (A × B × 1)
1212   _ = refl
1213
1214   _ : ∀ {A B C D E : Set} → sources (A → B → C → D → E)
1215     ≡ Σ A (λ _ → Σ B (λ _ → Σ C (λ _ → Σ D (λ _ → Σ E (λ _ → T)))))
1216   _ = refl

```

Design decision: Types starting with implicit arguments are *invariants*, not *constructors*.

```

1217   -- one implicit
1218   _ : sources (∀ {x : N} → x ≡ x) ≡ 0
1219   _ = refl
1220
1221   -- multiple implicits
1222   _ : sources (∀ {x y z : N} → x ≡ y) ≡ 0
1223   _ = refl

```

The third stage can now be formed.

```

1224   D3 = sources D2
1225
1226   3-sources : D3 ≡ λ (X : Set) → Σ z : 1 • Σ s : X • 0
1227   3-sources = refl

```

A.11.4 Stage 4: $\Sigma \rightarrow \mathcal{U}$ –Replacing Products with Sums.

```

1231   {-# TERMINATING #-}
1232   Σ→U : Term → Term
1233   Σ→U (def (quote Σ) (h1 :: h0 :: arg i A :: arg i1 (lam v (abs s x)) :: []))
1234     = def (quote _U_) (h1 :: h0 :: arg i A :: vArg (Σ→U (var-dec x)) :: [])
1235   -- Interpret "End" in do-notation to be an empty, impossible, constructor.
1236   Σ→U (def (quote T) _) = def (quote ⊥) []
1237   -- Walk under λ's and Π's.
1238   Σ→U (lam v (abs s x)) = lam v (abs s (Σ→U x))
1239   Σ→U (Π[ x : A ] Bx) = Π[ x : A ] Σ→U Bx
1240   {-# CATCHALL #-}
1241   Σ→U t = t
1242
1243   macro
1244     Σ→U : Term → Term → TC Unit.T
1245     Σ→U tm goal = normalise tm >>= m λ tm' → unify (Σ→U tm') goal
1246
1247   -- Unit tests
1248   _ : Σ→U (Π X : Set • (X → X)) ≡ (Π X : Set • (X → X)); _ = refl

```

```

1249   _ :  $\Sigma \rightarrow \mathcal{U}$  ( $\Pi X : \mathbf{Set} \bullet \Sigma s : X \bullet X$ )  $\equiv$  ( $\Pi X : \mathbf{Set} \bullet X \mathcal{U} X$ ) ; _ = refl
1250   _ :  $\Sigma \rightarrow \mathcal{U}$  ( $\Pi X : \mathbf{Set} \bullet \Sigma s : (X \rightarrow X) \bullet X$ )  $\equiv$  ( $\Pi X : \mathbf{Set} \bullet (X \rightarrow X) \mathcal{U} X$ ) ; _ = refl
1251   _ :  $\Sigma \rightarrow \mathcal{U}$  ( $\Pi X : \mathbf{Set} \bullet \Sigma z : X \bullet \Sigma s : (X \rightarrow X) \bullet \top \{\ell_0\}$ )  $\equiv$  ( $\Pi X : \mathbf{Set} \bullet X \mathcal{U} (X \rightarrow X) \mathcal{U} \perp$ ) ; _ = refl
1252
1253   D4 =  $\Sigma \rightarrow \mathcal{U}$  D3
1254
1255   4-unions : D4  $\equiv$   $\lambda X \rightarrow \mathbb{1} \mathcal{U} X \mathcal{U} \mathbb{0}$ 
1256   4-unions = refl

```

A.11.5 Stage 5: Fixpoint and proof that $\mathbb{D} \cong \mathbb{N}$.

```

1257   {-# NO_POSITIVITY_CHECK #-}
1258   data Fix {ℓ} (F : Set ℓ → Set ℓ) : Set ℓ where
1259     μ : F (Fix F) → Fix F
1260
1261   ℙ = Fix D4
1262
1263   -- Pattern synonyms for more compact presentation
1264   pattern zeroD = μ (inj1 tt) -- : ℙ
1265   pattern sucD e = μ (inj2 (inj1 e)) -- : ℙ → ℙ
1266
1267   to : ℙ → ℕ
1268   to zeroD = 0
1269   to (sucD x) = suc (to x)
1270
1271   from : ℕ → ℙ
1272   from zero = zeroD
1273   from (suc n) = sucD (from n)
1274
1275   toofrom : ∀ n → to (from n)  $\equiv$  n
1276   toofrom zero = refl
1277   toofrom (suc n) = cong suc (toofrom n)
1278
1279   fromto : ∀ d → from (to d)  $\equiv$  d
1280   fromto zeroD = refl
1281   fromto (sucD x) = cong sucD (fromto x)

```

A.11.6 *termtype and Inj macros*. We summarise the stages together into one macro: “termtype : UnaryFunctor \rightarrow Type”.

```

1285   macro
1286     termtype : Term → Term → TC Unit.T
1287     termtype tm goal =
1288       normalise tm
1289       >>= m  $\lambda$  tm' → unify goal (def (quote Fix) ((vArg ( $\Sigma \rightarrow \mathcal{U}_0$  (sources1 tm')))) :: []))

```

It is interesting to note that in place of pattern clauses, say for languages that do not support them, we would resort to “fancy injections”.

```

1293   Inj0 : ℕ → Term → Term
1294   Inj0 zero c = con (quote inj1) (arg (arg-info visible relevant) c :: [])
1295   Inj0 (suc n) c = con (quote inj2) (vArg (Inj0 n c) :: [])
1296
1297   -- Duality!
1298   -- i-th projection: proj1 ∘ (proj2 ∘ ⋯ ∘ proj2)
1299   -- i-th injection: (inj2 ∘ ⋯ ∘ inj2) ∘ inj1

```

```

1301 macro
1302   Inj :  $\mathbb{N} \rightarrow \text{Term} \rightarrow \text{Term} \rightarrow \text{TC Unit.T}$ 
1303   Inj n t goal = unify goal ((con (quote  $\mu$ ) []) app (Inj0 n t))

```

With this alternative, we regain the “user chosen constructor names” for \mathbb{D} :

```

1305 startD :  $\mathbb{D}$ 
1306 startD = Inj 0 (tt { $\ell_0$ })
1307
1308 nextD' :  $\mathbb{D} \rightarrow \mathbb{D}$ 
1309 nextD' d = Inj 1 d
1310

```

A.12 Monoids

A.12.1 Context.

```

1314 Monoid :  $\forall \ell \rightarrow \text{Context } (\ell \text{ suc } \ell)$ 
1315 Monoid  $\ell$  = do Carrier  $\leftarrow$  Set  $\ell$ 
1316   Id  $\leftarrow$  Carrier
1317   _ $\oplus$ _  $\leftarrow$  (Carrier  $\rightarrow$  Carrier  $\rightarrow$  Carrier)
1318   leftId  $\leftarrow$   $\forall \{x : \text{Carrier}\} \rightarrow x \oplus \text{Id} \equiv x$ 
1319   rightId  $\leftarrow$   $\forall \{x : \text{Carrier}\} \rightarrow \text{Id} \oplus x \equiv x$ 
1320   assoc  $\leftarrow$   $\forall \{x y z\} \rightarrow (x \oplus y) \oplus z \equiv x \oplus (y \oplus z)$ 
1321   End { $\ell$ }

```

A.12.2 Termtypes.

```

1323 M : Set
1324 M = termtree (Monoid  $\ell_0$  :waist 1)
1325 {- ie Fix ( $\lambda X \rightarrow 1$  -- Id, nil leaf
1326    $\cup X \times X \times 1$  --  $\oplus$ _, branch
1327    $\cup 0$  -- src of leftId
1328    $\cup 0$  -- src of rightId
1329    $\cup X \times X \times 0$  -- src of assoc
1330    $\cup 0$ ) -- the “End { $\ell$ }”
1331 -}
1332
1333 -- Pattern synonyms for more compact presentation
1334 pattern emptyM =  $\mu$  (inj1 tt) -- : M
1335 pattern branchM l r =  $\mu$  (inj2 (inj1 (l, r, tt))) -- : M  $\rightarrow$  M  $\rightarrow$  M
1336 pattern absurdM a =  $\mu$  (inj2 (inj2 (inj2 (inj2 a)))) -- absurd values of 0
1337
1338 data TreeSkeleton : Set where
1339   empty : TreeSkeleton
1340   branch : TreeSkeleton  $\rightarrow$  TreeSkeleton  $\rightarrow$  TreeSkeleton

```

A.12.3 $M \cong \text{TreeSkeleton}$.

```

1342 M $\rightarrow$ Tree : M  $\rightarrow$  TreeSkeleton
1343 M $\rightarrow$ Tree emptyM = empty
1344 M $\rightarrow$ Tree (branchM l r) = branch (M $\rightarrow$ Tree l) (M $\rightarrow$ Tree r)
1345 M $\rightarrow$ Tree (absurdM (inj1 ()))
1346 M $\rightarrow$ Tree (absurdM (inj2 ()))
1347
1348 M $\leftarrow$ Tree : TreeSkeleton  $\rightarrow$  M
1349 M $\leftarrow$ Tree empty = emptyM
1350 M $\leftarrow$ Tree (branch l r) = branchM (M $\leftarrow$ Tree l) (M $\leftarrow$ Tree r)
1351
1352 M $\leftarrow$ Tree  $\circ$  M $\rightarrow$ Tree :  $\forall m \rightarrow M \leftarrow \text{Tree } (M \rightarrow \text{Tree } m) \equiv m$ 

```

```

1353 M←TreeoM→Tree emptyM = refl
1354 M←TreeoM→Tree (branchM l r) = cong2 branchM (M←TreeoM→Tree l) (M←TreeoM→Tree r)
1355 M←TreeoM→Tree (absurdM (inj1 ()))
1356 M←TreeoM→Tree (absurdM (inj2 ()))
1357
1358 M→TreeoM←Tree : ∀ t → M→Tree (M←Tree t) ≡ t
1359 M→TreeoM←Tree empty = refl
1360 M→TreeoM←Tree (branch l r) = cong2 branch (M→TreeoM←Tree l) (M→TreeoM←Tree r)

```

A.13 :kind

```

1363 data Kind : Set where
1364   'record   : Kind
1365   'typeclass : Kind
1366   'data     : Kind
1367
1368 macro
1369   _:kind_ : Term → Term → Term → TC Unit.T
1370   _:kind_ t (con (quote 'record) _) goal = normalise (t app (quoteTerm 0))
1371   >>= m λ t' → unify (waist-helper 0 t') goal
1372   _:kind_ t (con (quote 'typeclass) _) goal = normalise (t app (quoteTerm 1))
1373   >>= m λ t' → unify (waist-helper 1 t') goal
1374   _:kind_ t (con (quote 'data) _) goal = normalise (t app (quoteTerm 1))
1375   >>= m λ t' → normalise (waist-helper 1 t')
1376   >>= m λ t'' → unify goal (def (quote Fix) ((vArg (Σ→U0 (sources1 t'')))) :: []))
1377   _:kind_ t _ goal = unify t goal

```

Informally, `_:kind_` behaves as follows:

```

1378 C :kind 'record   = C :waist 0
1379 C :kind 'typeclass = C :waist 1
1380 C :kind 'data     = termtype (C :waist 1)

```

A.14 termtype PointedSet ≅ 1

```

1384 -- termtype (PointedSet) ≅ T !
1385 One : Context (ℓsuc ℓ0)
1386 One   = do Carrier ← Set ℓ0
1387       point ← Carrier
1388       End {ℓ0}
1389
1390 One : Set
1391 One = termtype (One :waist 1)
1392
1393 view1 : One → 1
1394 view1 emptyM = tt

```

A.15 The Termtypes of Graphs is Vertex Pairs

From simple graphs (relations) to a syntax about them: One describes a simple graph by presenting edges as pairs of vertices!

```

1399 PointedOver2 : Set → Context (ℓsuc ℓ0)
1400 PointedOver2 ≡ = do Carrier ← Set ℓ0
1401               relation ← (≡ → ≡ → Carrier)
1402               End {ℓ0}

```

```

1405  $\mathbb{P}_2 : \text{Set} \rightarrow \text{Set}$ 
1406  $\mathbb{P}_2 X = \text{termtpe} (\text{PointedOver}_2 X : \text{waist } 1)$ 
1407
1408  $\text{pattern } \_ \rightleftharpoons \_ x y = \mu (\text{inj}_1 (x, y, \text{tt}))$ 
1409
1410  $\text{view}_2 : \forall \{X\} \rightarrow \mathbb{P}_2 X \rightarrow X \times X$ 
1411  $\text{view}_2 (x \rightleftharpoons y) = x, y$ 
1412

```

A.16 No ‘constants’, whence a type of infinitely branching terms

```

1413
1414  $\text{PointedOver}_3 : \text{Set} \rightarrow \text{Context } (\ell_0)$ 
1415  $\text{PointedOver}_3 \Xi = \text{do relation} \leftarrow (\Xi \rightarrow \Xi \rightarrow \Xi)$ 
1416  $\text{End } \{\ell_0\}$ 
1417
1418  $\mathbb{P}_3 : \text{Set}$ 
1419  $\mathbb{P}_3 = \text{termtpe } (\lambda X \rightarrow \text{PointedOver}_3 X \emptyset)$ 
1420

```

A.17 \mathbb{P}_2 again!

```

1421
1422  $\text{PointedOver}_4 : \text{Context } (\ell \text{ suc } \ell_0)$ 
1423  $\text{PointedOver}_4 = \text{do } \Xi \leftarrow \text{Set}$ 
1424  $\text{Carrier} \leftarrow \text{Set } \ell_0$ 
1425  $\text{relation} \leftarrow (\Xi \rightarrow \Xi \rightarrow \text{Carrier})$ 
1426  $\text{End } \{\ell_0\}$ 
1427
1428 -- The current implementation of “termtpe” only allows for one “Set” in the body.
1429 -- So we lift both out; thereby regaining  $\mathbb{P}_2$ !
1430
1431  $\mathbb{P}_4 : \text{Set} \rightarrow \text{Set}$ 
1432  $\mathbb{P}_4 X = \text{termtpe } ((\text{PointedOver}_4 : \text{waist } 2) X)$
