What is the problem?

What is *in a* monoid?

People work with monoids at various levels of exposure ...

What is *in* a monoid?

People work with monoids at various levels of exposure ...

- “Let M be a monoid, ...”

What is *in* a monoid?

People work with monoids at various levels of exposure ...

- “Let M be a monoid, ...”
- “Given a monoid over \mathbb{N} , ...”

What is *in* a monoid?

People work with monoids at various levels of exposure ...

- “Let M be a monoid, ...”
- “Given a monoid over \mathbb{N} , ...”
- “Consider *the* monoid $(\mathbb{N}, +)$, ...”
 - (Unique viz proof irrelevance.)

What is *in* a monoid?

People work with monoids at various levels of exposure ...

- “Let M be a monoid, ...”
- “Given a monoid over \mathbb{N} , ...”
- “Consider *the* monoid $(\mathbb{N}, +)$, ...”
 - (Unique viz proof irrelevance.)
- “Consider *the* monoid $(\mathbb{N}, +, 0)$, ...”

“A monoid consists of a collection Carrier, an operation, ...”?

```
record Monoid0 : Set1 where
  field Carrier : Set
        _◦_      : Carrier → Carrier → Carrier
        Id       : Carrier
        lid      : ∀ {x} → Id ◦ x ≡ x
        rid      : ∀ {x} → x ◦ Id ≡ x
        assoc    : ∀ {x y z} → (x ◦ y) ◦ z ≡ x ◦ (y ◦ z)
```

Use-case: The category of monoids.

“A monoid over a given collection `Carrier` and operation `_⋈_` is given by ensuring there is a selected point ...”?

```
record Monoid1
  (Carrier : Set)      : Set  where
  field -- ←←←←←←←←←←←←←←←← Change here
    _⋈_      : Carrier → Carrier → Carrier
    Id       : Carrier
    lid      : ∀ {x} → Id ⋈ x ≡ x
    rid      : ∀ {x} → x ⋈ Id ≡ x
    assoc    : ∀ {x y z} → (x ⋈ y) ⋈ z ≡ x ⋈ (y ⋈ z)
```

Use-case: Sharing the carrier type

Or ... ?

```
record Monoid2
  (Carrier : Set)
  (_◊_      : Carrier → Carrier → Carrier) : Set where
field -- ←←←←←←←←←←←←←←←← Change here
  Id      : Carrier
  lid     : ∀ {x} → Id ◊ x ≡ x
  rid     : ∀ {x} → x ◊ Id ≡ x
  assoc   : ∀ {x y z} → (x ◊ y) ◊ z ≡ x ◊ (y ◊ z)
```

Use-case: The additive monoid on the Natural numbers

Or ... ?

```
record Monoid3
  (Carrier : Set)
  (_◊_      : Carrier → Carrier → Carrier)
  (Id      : Carrier)      : Set where
field -- ←←←←←←←←←←←←←←←← Change here
  lid      : ∀ {x} → Id ◊ x ≡ x
  rid      : ∀ {x} → x ◊ Id ≡ x
  assoc    : ∀ {x y z} → (x ◊ y) ◊ z ≡ x ◊ (y ◊ z)
```

Structures are meaninglessly parameterized from a mathematical perspective. [...] That is, what is bundled cannot be later opened up as a parameter. [...] This means that library designers are forced to take a conservative approach and expose as a parameter anything that any user might reasonably want exposed, because once it is bundled, it is not coming back.

—A Review of the Lean Theorem Prover, 2018-09-18

⇒ This is a problem we are solving!

Structures are meaninglessly parameterized from a mathematical perspective. [...] That is, what is bundled cannot be later opened up as a parameter. A Language Feature to Unbundle Data at Will (GPCE '19)

But perhaps Haskell's type system does not give the programmer sufficient tools to adequately express such ideas. As such, for the rest of this paper we will illustrate our ideas in Agda [2, 7]. For the monoid example, it seems that there are three contenders for the monoid interface:

```
record Monoid0 : Set1 where
  field
    Carrier : Set
    _|-_      : Carrier → Carrier → Carrier
    Id       : Carrier
    assoc    : ∀ {x y z}
              → (x § y) § z ≡ x § (y § z)
    leftId   : ∀ {x} → Id § x ≡ x
    rightId  : ∀ {x} → x § Id ≡ x

record Monoid1 (Carrier : Set) : Set where
  field
    _|-_      : Carrier → Carrier → Carrier
    Id       : Carrier
    assoc    : ∀ {x y z}
              → (x § y) § z ≡ x § (y § z)
    leftId   : ∀ {x} → Id § x ≡ x
    rightId  : ∀ {x} → x § Id ≡ x

record Monoid2
  (Carrier : Set)
  (_|-_ : Carrier → Carrier → Carrier)
  : Set where
  field
    Id       : Carrier
    assoc    : ∀ {x y z}
              → (x § y) § z ≡ x § (y § z)
    leftId   : ∀ {x} → Id § x ≡ x
    rightId  : ∀ {x} → x § Id ≡ x
```

In Monoid₀, we will call Carrier “bundled up”, while we call it “exposed” in Monoid₁ and Monoid₂. The bundled-up version allows us to speak of a monoid, rather than a monoid on a given type which is captured by Monoid₁. While Monoid₂ exposes both the carrier and the composition operation, we

automation, may want to use the associated datatype for syntax. For example, the syntax of closed monoid terms can be expressed, using trees, as follows.

```
data Monoid3 : Set where
  _|-_ : Monoid3 → Monoid3 → Monoid3
  Id   : Monoid3
```

We can see that this can be obtained from Monoid₀ by discarding the fields denoting equations, then turning the remaining fields into constructors.

We show how these different presentations can be derived from a single PackageFormer declaration via a generative meta-program integrated into the most widely-used Agda “IDE”, the Emacs mode for Agda. In particular, if one were to explicitly write M different bundlings of a package with N constants then one would write nearly $N \times M$ lines of code, yet this quadratic count becomes linear $N + M$ by having a single package declaration of N constituents with M subsequent instantiations. We hope that reducing such duplication of effort, and of potential maintenance burden, will be beneficial to the software engineering of large libraries of formal code — and consider it the main contribution of our work.

2 PackageFormers — Being Non-committal as Much as Possible

We claim that the above monoid-related pieces of Agda code can be unified as a single declaration which does not distinguish between parameters and fields, where PackageFormer is a keyword with similar syntax as record:

```
PackageFormer MonoidP : Set1 where
  Carrier : Set
  _|-_      : Carrier → Carrier → Carrier
  Id       : Carrier
  assoc    : ∀ {x y z}
            → (x § y) § z ≡ x § (y § z)
  leftId   : ∀ {x} → Id § x ≡ x
  rightId  : ∀ {x} → x § Id ≡ x
```

(For clarity, this and other non-native Agda syntax is left uncoloured.)

The Definition of a Monoid

```
PackageFormer MonoidP : Set1 where
  Carrier : Set
  _⋄_      : Carrier → Carrier → Carrier
  Id      : Carrier
  assoc   : ∀ {x y z} → (x ⋄ y) ⋄ z ≡ x ⋄ (y ⋄ z)
  leftId  : ∀ {x} → Id ⋄ x ≡ x
  rightId : ∀ {x} → x ⋄ Id ≡ x
```

The Definition of a Monoid

Primary Lessons Learned

1. Waist
2. Termtypes
3. Pragmatic

The Unbundling Problem —in Agda

What is “the” monoid on the natural numbers?

Some types can be viewed as a monoid in more than one way, e.g. both addition and multiplication on numbers. In such cases we often define newtypes and make those instances of Monoid, e.g. Sum and Product. —[Hackage Data.Monoid](#)

`Sum` $\alpha \cong \alpha$ `{- and -}` `Product` $\alpha \cong \alpha$

Alternate Solution to Multiple Monoid Instance Problem

Start with *fully bundled* `Monoid` then *expose fields as parameters on the fly*.

Alternate Solution to Multiple Monoid Instance Problem

Start with *fully bundled* `Monoid` then *expose fields as parameters on the fly*.

Reflection!

- Unfortunately, current mechanism cannot touch `record`-s *directly*.
- But every record is a Σ -type. . .

Records as $\Pi^w\Sigma$ -types —Partitioned Contexts

- Instead of the nice *syntactic sugar*

```
record R ( $\varepsilon^1 : \tau^1$ )  $\cdots$  ( $\varepsilon^w : \tau^w$ ) : Set
```

```
  where
```

```
    field
```

```
       $\varepsilon^{w+1} : \tau^{w+1}$ 
```

```
       $\vdots$ 
```

```
       $\varepsilon^{w+k} : \tau^{w+k}$ 
```

Records as $\Pi^w \Sigma$ -types — Partitioned Contexts

- Instead of the nice *syntactic sugar*

record **R** ($\varepsilon^1 : \tau^1$) \cdots ($\varepsilon^w : \tau^w$) : **Set**

where

field

$\varepsilon^{w+1} : \tau^{w+1}$

\vdots

$\varepsilon^{w+k} : \tau^{w+k}$

- Use a rawer form —*EEK!*

R : $\Pi \varepsilon^1 : \tau^1 \bullet \cdots \bullet \Pi \varepsilon^w : \tau^w \bullet$ **Set**

R \cong $\lambda \varepsilon^1 : \tau^1 \bullet \cdots \bullet \lambda \varepsilon^w : \tau^w$

$\bullet \Sigma \varepsilon^{w+1} : \tau^{w+1} \bullet \cdots \bullet \Sigma \varepsilon^{w+k} : \tau^{w+k}$

$\bullet \mathbb{1}$

A Pragmatic Notation —Contexts

```
Monoid : Context  $\ell_1$   
Monoid = do Carrier  $\leftarrow$  Set  
    _ $\circ$ _       $\leftarrow$  (Carrier  $\rightarrow$  Carrier  $\rightarrow$  Carrier)  
    Id        $\leftarrow$  Carrier  
    leftId    $\leftarrow$   $\forall$  (x : Carrier)  $\rightarrow$  x  $\circ$  Id  $\equiv$  x  
    rightId   $\leftarrow$   $\forall$  (x : Carrier)  $\rightarrow$  Id  $\circ$  x  $\equiv$  x  
    assoc     $\leftarrow$   $\forall$  (x y z)  $\rightarrow$  (x  $\circ$  y)  $\circ$  z  $\equiv$  x  $\circ$  (y  $\circ$  z)  
End { $\ell$ }
```

What is `Context`?

1. “Contexts” are exposure-indexed types

$$\text{Context} = \lambda \ell \rightarrow (\text{waist} : \mathbb{N}) \rightarrow \text{Set } \ell$$

2. The “empty context” is the unit type

$$\text{End} : \forall \{\ell\} \rightarrow \text{Context } \ell$$
$$\text{End } \{\ell\} = \lambda _ \rightarrow \mathbb{1} \{\ell\}$$

3. `do`-notation!

$$_ >>= _ : \forall \{a \ b\}$$
$$\rightarrow (\Gamma : \text{Context } a)$$
$$\rightarrow (\forall \{n\} \rightarrow \Gamma \ n \rightarrow \text{Context } b)$$
$$\rightarrow \text{Context } (a \uplus b)$$
$$(\Gamma >>= f) \text{ zero} = \sum \gamma : \Gamma \ 0 \bullet f \ \gamma \ 0$$
$$(\Gamma >>= f) (\text{suc } n) = \prod \gamma : \Gamma \ n \bullet f \ \gamma \ n$$

Using Contexts —*reification*

```
Monoid : Context
Monoid = do C ← Set; _◦_ : C → C → C; Id ← C; ...
```

```

Example Instance —Additive Naturals

```
 $\mathbb{N}_+$  : (Monoid  $\ell_0$  :waist 1)  $\mathbb{N}$   
 $\mathbb{N}_+$  = <  $_{-}+_{-}$  --  $_{-}\circ_{-}$   
      , 0 --  $Id$   
      , +-identity'  
      , +-identityr  
      , +-assoc  
      >
```

Summary: Solve the unbundling problem

'Unbundle' module fields as if they were parameters 'on the fly'

Summary: Solve the unbundling problem

‘Unbundle’ module fields as if they were parameters ‘on the fly’

```
DynamicSystem : Context  $\ell_1$   
DynamicSystem  
  = do State  $\leftarrow$  Set  
      start  $\leftarrow$  State  
      next  $\leftarrow$  (State  $\rightarrow$  State)  
      End
```

Summary: Solve the unbundling problem

‘Unbundle’ module fields as if they were parameters ‘on the fly’

```
DynamicSystem : Context  $\ell_1$   
DynamicSystem  
  = do State  $\leftarrow$  Set  
      start  $\leftarrow$  State  
      next  $\leftarrow$  (State  $\rightarrow$  State)  
  End
```

```
 $\mathcal{N}^0$  : DynamicSystem :waist 0  
 $\mathcal{N}^0$  =  $\langle \mathbb{N}, 0, \text{suc} \rangle$ 
```

```
 $\mathcal{N}^1$  : (DynamicSystem :waist 1)  $\mathbb{N}$   
 $\mathcal{N}^1$  =  $\langle 0, \text{suc} \rangle$ 
```

```
 $\mathcal{N}^2$  : (DynamicSystem :waist 2)  $\mathbb{N}$  0  
 $\mathcal{N}^2$  =  $\langle \text{suc} \rangle$ 
```

```
 $\mathcal{N}^3$  : (DynamicSystem :waist 3)  $\mathbb{N}$  0  
   $\hookrightarrow$  suc  
 $\mathcal{N}^3$  =  $\langle \rangle$ 
```

Without redefining `DynamicSystem`, we are able to **fix** some of its *fields* by making them into *parameters*!

GADTs are Contexts too!

From Contexts to GADTS

Monoid

\rightsquigarrow

`do C ← Set; \circ : C → C → C; Id : C; ...`

\rightsquigarrow

`λ C : Set • Σ \circ : C → C → C • Σ Id : C • ...`

```

\rightsquigarrow

```
 $\mu$  C : Set •  $C \times C \uplus C \uplus \mathbb{1}$ 
```

Monoids give rise to tree skeletons / Context

```
Monoid :  $\forall \ell \rightarrow$  Context ( $\ell$ suc  $\ell$ )  
Monoid  $\ell$  = do Carrier  $\leftarrow$  Set  $\ell$   
             _ $\circ$ _       $\leftarrow$  (Carrier  $\rightarrow$  Carrier  $\rightarrow$  Carrier)  
             Id        $\leftarrow$  Carrier  
             leftId    $\leftarrow$   $\forall \{x : \text{Carrier}\} \rightarrow \text{Id} \circ x \equiv x$   
             rightId   $\leftarrow$   $\forall \{x : \text{Carrier}\} \rightarrow x \circ \text{Id} \equiv x$   
             assoc      $\leftarrow$   $\forall \{x\ y\ z\} \rightarrow (x \circ y) \circ z \equiv x \circ (y \circ z)$   
             End { $\ell$ }
```

Monoids give rise to tree skeletons / Termtree

```
 $\mathbb{M}$  : Set
 $\mathbb{M}$  = termtree (Monoid  $\ell_0$  :waist 1)

that-is :  $\mathbb{M}$ 
   $\equiv$  Fix ( $\lambda X \rightarrow$ 
    --  $\_ \oplus \_$ , branch
     $X \times X \times \mathbb{1}$ 
    -- Id, nil leaf
     $\uplus \mathbb{1}$ 
    -- invariant leftId
     $\uplus \mathbb{0}$ 
    -- invariant rightId
     $\uplus \mathbb{0}$ 
    -- invariant assoc
     $\uplus \mathbb{0}$ 
    -- the “End  $\{\ell\}$ ”
     $\uplus \mathbb{0}$ )

that-is = refl
```

Monoids give rise to tree skeletons / Readability

```
-- : M
pattern emptyM
  =  $\mu$  (inj2 (inj1 tt))

-- : M → M → M
pattern branchM l r
  =  $\mu$  (inj1 (l , r , tt))

-- absurd 0-values
pattern absurdM a
  =  $\mu$  (inj2 (inj2 (inj2 (inj2 a))))
```

Monoids give rise to tree skeletons / $\text{termtype Monoid} \cong \text{TreeSkeleton}$

```
data TreeSkeleton : Set where
  empty   : TreeSkeleton
  branch  : TreeSkeleton → TreeSkeleton → TreeSkeleton
```

- “doing nothing”

```
to : M → TreeSkeleton
to emptyM          = empty
to (branchM l r) = branch (to l) (to r)
to (absurdM (inj1 ()))
to (absurdM (inj2 ()))
```

- “doing nothing”

```
from : TreeSkeleton → M
from empty          = emptyM
from (branch l r) = branchM (from l) (from r)
```

Summary: Contexts \mapsto {Records, ADTs}

Bring algebraic data types under the umbrella of grouping mechanisms:

```
-- Pattern synonyms for more compact presentation
pattern startD =  $\mu$  (inj1 tt)      -- :  $\mathbb{D}$ 
pattern nextD e =  $\mu$  (inj2 (inj1 e)) -- :  $\mathbb{D} \rightarrow \mathbb{D}$ 
trivial :  $\mathbb{D} \cong \mathbb{N}$ 
```

Summary: Common data-structures as free termtypes

'theory' τ	'data structure' termtypes τ
pointed set	$\mathbb{1}$
dynamic system	\mathbb{N}
monoid	tree skeletons
collections	lists
graphs	(homogeneous) pairs
actions	infinite streams

Many more theories τ to explore and see what data structures arise!

Conclusions

“All” module constructions are born from Context

“All” module constructions are born from Context

- Context: “name-type pairs”

```
do S ← Set; s ← S; n ← (S → S); End
```

“All” module constructions are born from Context

- Context: “name-type pairs”

`do S ← Set; s ← S; n ← (S → S); End`

$\Downarrow \quad \Downarrow \quad \Downarrow \quad \Downarrow \quad \Downarrow$

- Record Type: “bundled-up data”

`Σ S : Set • Σ s : S • Σ n : S → S • 1`

- Function Type: “a type of functions”

`Π S • Σ s : S • Σ n : S → S • 1`

- Type constructor: “a function on types”

`λ S • Σ s : S • Σ n : S → S • 1`

- Algebraic datatype: “a descriptive syntax”

`data D : Set where s : D; n : D → D`

Contributions

0. Identify the **module design patterns** used by DTL practitioners
1. Demonstrate that there is an expressive yet minimal set of primitives which allow common module constructions to be defined
2. Bring **algebraic data types** under the umbrella of grouping mechanisms
3. The ability to 'unbundle' module fields as if they were parameters 'on the fly'
4. Show that common data-structures are **mechanically the (free) termtypes** of common modules
5. Demonstrate that there is a **practical implementation** of such a framework
6. Finally, the resulting framework is *mostly* **type-theory agnostic**.
